KEYWORDS
Q wave, QTC interval, QRS Frontal axis, ST segment

ABSTRACT
In pregnant women, large number of local and systemic changes are known to occur. These changes will continue throughout pregnancy especially cardiovascular changes. Electrocardiography is one of the simplest techniques used to detect ischemic heart diseases, hypertensive heart diseases & asymptomatic arrhythmias. We included 150 pregnant women, 50 in each trimester and were compared with 50 age matched non pregnant women. ECG was recorded in all 12 leads. The values were expressed as Mean ± SD and Z – Test was used for comparison between control and study group. Categorical data was analyzed by Chi – square test. A ‘p’ value of 0.05 or less was considered as statistically significant. A statistically significant increase in QTc interval was observed. An increase in the QTc interval may be due to tachycardia. QRS Frontal axis showed a statistically significant decrease in 1st, 2nd and 3rd trimesters (p<0.001) of pregnancy when compared to non pregnant women. With increase in gestational age, position of heart changes from vertical to intermediate indicating that heart shifted to left with increase in gestational period. Occurrence of Q wave in lead III showed a statistically significant increase in 2nd (p<0.05) and 3rd trimesters (p<0.001) when compared to 1st trimester of pregnancy and control. These changes may be either due to an increase in the circulating vasopressor agents or may reflect diaphragmatic changes that have been associated with pregnancy.

Introduction
Pregnancy is considered to be the most beautiful and enriching experience in the life of a woman. It is characterized by profound changes in the function of virtually every regulatory system in the human body.
In pregnant women, large number of local and systemic changes are known to occur. These changes will continue throughout pregnancy especially cardiovascular changes such as increase in heart rate, cardiac output and intravascular volume.

The physiological changes during pregnancy facilitate the adaptation of the cardiovascular system to the increased metabolic needs of the mother enabling adequate delivery of oxygenated blood to the peripheral tissues and to the fetus. In the absence of these adaptations, incidence of gestational complications such as fetal growth restriction and pregnancy induced hypertension are known to increase.

Heart diseases contribute significantly to maternal mortality throughout the world. Although heart diseases rarely occur during pregnancy, it is a fact that greater number of women with known or potential heart diseases are becoming pregnant. Hemodynamic changes during pregnancy play a major role in the induction of arrhythmias. The increased incidence of arrhythmias during pregnancy is also reported.

Heart diseases during pregnancy remain a serious problem. One of the important tools for the diagnosis of heart diseases is recording electrocardiogram. In order to make use of it accurately, knowledge about ECG changes during normal pregnancy is a must. Electrocardiography is one of the simplest techniques used to detect ischemic heart diseases, hypertensive heart diseases & asymptomatic arrhythmias.

**Materials and Methods**

A cross sectional study was conducted in the Department of Physiology, Shri B.M.Patil Medical College, Hospital and Research Centre, Bijapur. Duration of the study was one year.

The study was undertaken to determine the ECG changes in 1st, 2nd & 3rd trimesters of pregnancy. The observations were compared with age matched healthy non pregnant women.

**Method of Collection of data**

**Study Group:** 150 pregnant women in the age group of 20-35yrs who were attending the OPD of OBGy of Shri B.M. Patil Medical College were included in the study group. The study group was in turn divided into 3 subgroups. Each subgroup comprising of 50 women in first, second and third trimesters of pregnancy.

**Control Group:** It was comprising of another apparently healthy age matched 50 non pregnant women.

The nature and purpose of the study were explained to the subjects who had volunteered for the study. From each participant an informed consent was obtained. A thorough physical & systemic examination of each subject was done (in particular, cardiovascular and respiratory system). Recordings were taken during morning hours between 9 am to 12 Noon.

**Inclusion Criteria**

- Apparently healthy subjects of Indian origin were included in the study.
- The apparent health status of the subject were determined through thorough clinical examination and history taking.

**Exclusion Criteria**

1. Subjects with history or clinical signs of cardiovascular diseases.
2. Subjects with acute respiratory infection in the previous three months.
3. Subject with history of diabetes mellitus, hypertension.
4. Subjects with history of tobacco consumption in any form.
5. Subjects with history of alcohol intake.
7. Subjects with obesity.
8. Subjects with moderate to severe anemia.

**Following parameters were recorded in each subject**

Height (in centimeters), Weight (in kilograms), Body surface area in square meters using Dubois nomogram, Body Mass Index in kilograms/ meter using Quetelet Index, Resting pulse rate was expressed as bpm, Blood pressure (in mm Hg). It was measured by mercurial sphygmomanometer (diamond make) by palpatory and auscultatory method.

**Recording of Electrocardiogram 22**

ECG was recorded after giving 5 minutes of rest to the subject to allay anxiety. ECG was recorded in all 12 leads i.e, 3 Standard Bipolar Limb Leads I: II & III, 3 Unipolar augmented limb leads: aVR, aVL, aVF and 6 Precordial leads: VI to V6, by connecting electrodes to left arm, right arm, left leg and right leg in supine position.

**Statistical Analysis**

The results were expressed as Mean + SD for continuous data and number and percentages for categorial data. Z test was used for comparison between control and study groups and Z test was used for comparison within the study group. Categorial data was analysed by Chi-square test.

A ‘p’ value of 0.05 or less was considered as statistically significant.

**Results and Discussion**

**QTc Interval**

QTc interval (sec) in controls, pregnant women in 1st, 2nd and 3rd trimesters were 0.38 + 0.01, 0.39 + 0.01, 0.40 + 0.01 and 0.41 + 0.01 respectively (Table 2). QTc interval showed a statistically significant increase 1st, 2nd and 3rd trimester of pregnancy when compared to control group (p< 0.001) (Table 3). Similarly, a statistically significant increase in QTc interval was observed in 2nd and 3rd trimester (p< 0.001) of pregnancy when compared to 1st trimester and also in 3rd trimester (p< 0.001) of pregnancy when compared to 2nd trimester.

**QRS Frontal axis**

QRS Frontal axis (degrees) in control, pregnant women in 1st , 2nd and 3rd trimesters were 64.56 + 7.66, 60.48 + 11.05, 55.70 + 12.61 and 45.4 + 22.54 respectively (Table 2). QRS Frontal axis showed a statistically significant decrease in 1st, 2nd and 3rd trimesters (p<0.001) of pregnancy when compared to non pregnant women (Table 3). Similarly, a statistically significant decrease in QRS frontal axis was observed in 2nd and 3rd trimesters (p<0.001) when compared 1st trimester and 3rd trimester when compared to 2nd trimester of pregnancy (p<0.001).

**ST segment**

In the present study, we observed ST segment depression in 2nd and 3rd trimesters of pregnancy i.e 4 subjects in 2nd trimester and 6 subjects in 3rd trimester. None of subjects in control group and in 1st trimester of pregnancy showed ST segment depression. There was no statistically significant difference between control and study groups or within the subgroups of study group (p>0.05).
Occurrence of Q wave in limb leads

**Lead I**

**Control:** Q wave was noted in 6% of the subjects.

**1st Trimester:** Q wave was noted in 4%,
**2nd Trimester:** Q wave was noted in 8% and
**3rd Trimester:** Q wave was noted in 10% of the subjects

Occurrence of Q wave in lead I showed a slight increase in 2nd and 3rd trimesters of pregnancy when compared to 1st trimester of pregnancy and control group. But, there was no significant statistical difference between the groups (p>0.05), (Table 1).

**Lead II**

**Control:** Q wave was noted in 26% of the subjects.

**1st Trimester:** Q wave was noted in 32%,
**2nd Trimester:** Q wave was noted in 44% and
**3rd Trimester:** Q wave was noted in 52% of the subjects.

Occurrence of Q wave in lead II showed a statistically significant increase in 2nd (p<0.05) and 3rd trimesters (p<0.001) when compared to 1st trimester of pregnancy and control group (Table 1).

**Lead III**

**Control:** Q wave was noted in 32% of the subjects.

**1st Trimester:** Q wave was noted in 36%,
**2nd Trimester:** Q wave was noted in 48% and
**3rd Trimester:** Q wave was noted in 58% of the subjects

Occurrence of Q wave in lead III showed a statistically significant increase in 2nd (p<0.05) and 3rd trimesters (p<0.001) when compared to 1st trimester of pregnancy and control group (Table 1).

Pregnancy is a normal physiological process. It induces widespread circulatory adaptations in the mothers. The pregnancy induced changes in the cardiovascular system develop primarily to meet the increased metabolic demands of mother & fetus.

Both structural and functional changes are known to occur in the heart and vessels due to pregnancy. Ventricular dimensions, heart rate, cardiac output, vascular compliance and capacitance will increase whereas peripheral resistance and blood pressure decrease during pregnancy. Many of these changes are induced by gestational hormonal milieu which influences vessel structure, basal tone and reactivity via receptors for chorionic gonadotropin, estradiol and progesterone located in vascular endothelium and smooth muscle.

Despite the increased work load on the heart during gestation, the healthy pregnant women have no impairment of cardiac reserve. An understanding of these changes and the mechanism involved would be helpful in deciding on the optimal management of pregnant women with preexisting cardiovascular diseases as well as potentially useful in the prevention of gestational complications associated with inadequate maternal hemodynamic adaptation.

Electrocardiography is one of basic tools in the investigation of cardiovascular diseases. The electrocardiogram during normal pregnancy may show wide variation from the normal accepted. These variations may
be due to the changed spatial arrangement of
the chest organs as well as changed
electrical properties of the
myocardium. These changes are in turn due to
sympathetic and hormonal modulation of
cardiac electrica.

**Q wave**

In the present study, there was a statistically
significant increase in occurrence of Q wave
in the 2nd and 3rd trimesters when
compared to 1st trimester of pregnancy and
the control group.

These changes may be either due to an
increase in the circulating vasopressor
agents or may reflect diaphragmatic changes
that have been associated with pregnancy.\(^{10}\)
The frequent occurring of Q wave during
pregnancy when compared to normal non
pregnant women may be to due altered
position of the heart.\(^{11}\)

Similar findings were reported by Misra J et
al \(^{12}\), Veille JC et al\(^{13}\), Carruth JE et al\(^{14}\) &
Singh AD\(^{11}\), in their studies.

**QRS Complex**

QRS Complex measurement had no
statistically significant difference in duration
either when compared between the study
and the control groups, nor between the
subgroups within study groups.

**ST segment**

In the present study, ST segment depression
was noticed in 4 subjects in 2nd trimester
and 6 subjects in the 3rd trimester of
pregnancy. There was no change in ST
segment in the subjects of control group and
1st trimester of pregnancy. There was no
statistically significant difference between
the control and the study groups or between
subgroups within study group.

One of the causes for ST segment
depression during pregnancy may be due to
electrolyte imbalance such as hypokalaemia
as a result of persistent vomiting.\(^{15}\)

It has been suggested that transient ST
segment depression is associated with
anxiety which may be a provoking stimulus
and that can be attributed to an endogenous
hypersensitivity. One of the mechanisms by
which adrenaline induces hypersensitivity is
by increasing oxygen demand by the
increased muscular action and coronary
dilation. Anxiety might be accompanied by
an increase in circulating humoral agents
which would directly affect myocardial
electrical activity.\(^{16}\)

Our findings are in accordance with the
observations made by Boyle DM et al \(^{\text{7}}\),
Veille JC et al\(^{13}\), Oram S et al\(^{15}\), Singh AD
et al\(^{11}\) in their study.

**QT Interval**

In our study, there was no statistically
significant increase or decrease in the QT
interval when compared between the control
and study groups or within the study group.

**QTc Interval**

QTc Interval in electrocardiogram reflects
the time taken for depolarization and
repolarization in the ventricular
myocardium. The QT interval when
corrected for heart rate is QTc.

It must be emphasized that the surface
electrocardiographic QTc interval reflects
complex and interrelated aspects of cardiac
electrophysiology, cardiac geometry, torso
shape, tissue impedance and biological signal processing.

In the present study, it was found that there was a statistically significant increase in QTc interval in 1st, 2nd and 3rd trimesters of pregnancy when compared to control group. There was also a statistically significant increase in QTc interval in 2nd and 3rd trimesters when compared to 1st trimester of pregnancy and also in the 3rd when compared to 2nd trimester of pregnancy.

It is first necessary to determine the normal range of QTc interval in healthy pregnant women. It seemed possible that the altered circulatory dynamics during pregnancy might have some effect on its duration. It appears that the physical and emotional stress during 9 months of pregnancy may be a factor in triggering heart rhythm disorders in some vulnerable women.

An increase in the QTc interval may be due to tachycardia. They must be considered as a complex consequence with changes in regulatory mechanisms during normal pregnancy. It is first necessary to determine the normal range of QTc interval in healthy pregnant women. It seemed possible that the altered circulatory dynamics during pregnancy might have some effect on its duration. It appears that the physical and emotional stress during 9 months of pregnancy may be a factor in triggering heart rhythm disorders in some vulnerable women.

QRS Frontal axis

In the present study, QRS axis showed a statistically significant decrease in the 1st, 2nd and 3rd trimesters of pregnancy when compared to non pregnant women. There was also a statistically significant decrease in the 3rd trimester when compared to 1st and 2nd trimester of pregnancy.

With increase in gestational age, position of heart changes from vertical to intermediate indicating that heart shifted to left with increase in gestational period.

The change in the electrical axis may be due to raise in the diaphragm during pregnancy. The changes in the left ventricular size and mass and associated increased volume may cause the apical impulse to be displaced to the left. Elevation and rotation of the heart resulting from the enlarging uterus and left axis shift in early pregnancy can be explained from the fact that there is an increased blood volume which in turn causes left ventricular load. Similar findings were also reported from Singh AD et al, Misra J et al, Lechmanova M et al & Carruth JE et al in their studies.
